

## Recursion

## Recursive Functions

### Recursive Functions

**Definition:** A function is called recursive if the body of that function calls itself, either directly or indirectly

**Implication:** Executing the body of a recursive function may require applying that function

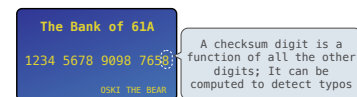

Drawing Hands, by M. C. Escher (lithograph, 1948)

### Digit Sums

$$2+0+1+9 = 12$$

- If a number  $a$  is divisible by 9, then  $\text{sum\_digits}(a)$  is also divisible by 9
- Useful for typo detection!

- Credit cards actually use the Luhn algorithm, which we'll implement after  $\text{sum\_digits}$

### The Problem Within the Problem

The sum of the digits of 6 is 6.

Likewise for any one-digit (non-negative) number (i.e.,  $< 10$ ).

The sum of the digits of 2019 is

That is, we can break the problem of summing the digits of 2019 into a **smaller instance of the same problem**, plus some extra stuff.

We call this **recursion**

### Sum Digits Without a While Statement

```
def split(n):  
    """Split positive n into all but its last digit and its last digit."""  
    return n // 10, n % 10
```

```
def sum_digits(n):  
    """Return the sum of the digits of positive integer n."""  
    if n < 10:  
        return n  
    else:  
        all_but_last, last = split(n)  
        return sum_digits(all_but_last) + last
```

## The Anatomy of a Recursive Function

- The `def` statement header is similar to other functions
- Conditional statements check for **base cases**
- Base cases are evaluated **without recursive calls**
- Recursive cases are evaluated **with recursive calls**

```
def sum_digits(n):
    """Return the sum of the digits of positive integer n."""
    if n < 10:
        return n
    else:
        all_but_last, last = split(n)
        return sum_digits(all_but_last) + last
```

(Demo)

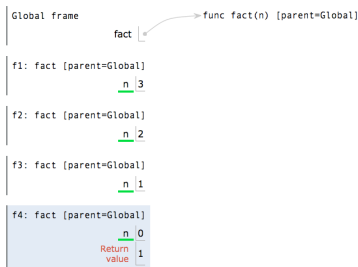

## Recursion in Environment Diagrams

## Recursion in Environment Diagrams

```
1 def fact(n):
2     if n == 0:
3         return 1
4     else:
5         return n * fact(n-1)
6
7 fact(3)
```

- The same function `fact` is called multiple times
- Different frames keep track of the different arguments in each call
- What `n` evaluates to depends upon the current environment
- Each call to `fact` solves a simpler problem than the last: smaller `n`

(Demo)

## Iteration vs Recursion

Iteration is a special case of recursion

$$4! = 4 \cdot 3 \cdot 2 \cdot 1 = 24$$

Using while:

```
def fact_iter(n):
    total, k = 1, 1
    while k <= n:
        total, k = total*k, k+1
    return total
```

Math:  $n! = \prod_{k=1}^n k$

Names: `n`, `total`, `k`, `fact_iter`

Using recursion:

```
def fact(n):
    if n == 0:
        return 1
    else:
        return n * fact(n-1)
```

$$n! = \begin{cases} 1 & \text{if } n = 0 \\ n \cdot (n-1)! & \text{otherwise} \end{cases}$$

Names: `n`, `fact`

## Verifying Recursive Functions

## The Recursive Leap of Faith

```
def fact(n):
    if n == 0:
        return 1
    else:
        return n * fact(n-1)
```

Is `fact` implemented correctly?

1. Verify the base case
2. Treat `fact` as a functional abstraction!
3. Assume that `fact(n-1)` is correct
4. Verify that `fact(n)` is correct

## Mutual Recursion

## The Luhn Algorithm

Used to verify credit card numbers

From Wikipedia: [http://en.wikipedia.org/wiki/Luhn\\_algorithm](http://en.wikipedia.org/wiki/Luhn_algorithm)

- **First:** From the rightmost digit, which is the check digit, moving left, double the value of every second digit; if product of this doubling operation is greater than 9 (e.g.,  $7 * 2 = 14$ ), then sum the digits of the products (e.g., 10:  $1 + 0 = 1$ , 14:  $1 + 4 = 5$ )
- **Second:** Take the sum of all the digits

1	3	8	7	4	3
2	3	1+6=7	7	8	3

= 30

The Luhn sum of a valid credit card number is a multiple of 10 (Demo)

## Recursion and Iteration

## Converting Recursion to Iteration

Can be tricky: Iteration is a special case of recursion.

Idea: Figure out what state must be maintained by the iterative function.

```
def sum_digits(n):  
    """Return the sum of the digits of positive integer n."""  
    if n < 10:  
        return n  
    else:  
        all_but_last, last = split(n)  
        return sum_digits(all_but_last) + last
```

What's left to sum

A partial sum

(Demo)

## Converting Iteration to Recursion

More formulaic: Iteration is a special case of recursion.

Idea: The state of an iteration can be passed as arguments.

```
def sum_digits_iter(n):  
    digit_sum = 0  
    while n > 0:  
        n, last = split(n)  
        digit_sum = digit_sum + last  
    return digit_sum
```

Updates via assignment become...

```
def sum_digits_rec(n, digit_sum):  
    if n == 0:  
        return digit_sum  
    else:  
        n, last = split(n)  
        return sum_digits_rec(n, digit_sum + last)
```

...arguments to a recursive call

## Order of Recursive Calls

## The Cascade Function

```

1 def cascade(n):
2   if n < 10:
3     print(n)
4   else:
5     print(n)
6     cascade(n//10)
7     print(n)
8   cascade(123)

```

(Demo)

Global frame

cascade ← func cascade(n) [parent=Global]

f1: cascade (parent=Global)  
n 123  
Return value None

f2: cascade (parent=Global)  
n 12  
Return value None

f3: cascade (parent=Global)  
n 1  
Return value None

• Each cascade frame is from a different call to cascade.  
• Until the Return value appears, that call has not completed.  
• Any statement can appear **before** or **after** the recursive call.

Program output:

```

123
12
1
12

```

Example: Inverse Cascade

## Two Definitions of Cascade

(Demo)

```

def cascade(n):
  if n < 10:
    print(n)
  else:
    print(n)
    cascade(n//10)
    print(n)

```

```

def cascade(n):
  print(n)
  if n >= 10:
    cascade(n//10)
    print(n)

```

- If two implementations are equally clear, then shorter is usually better
- In this case, the longer implementation is more clear (at least to me)
- When learning to write recursive functions, put the base cases first
- Both are recursive functions, even though only the first has typical structure

## Inverse Cascade

Write a function that prints an inverse cascade:

```

1         def inverse_cascade(n):
2         grow(n)
3         print(n)
4         shrink(n)
5
6         def f_then_g(f, g, n):
7         if n:
8           f(n)
9           g(n)
10
11        grow = lambda n: f_then_g(grow, shrink, n)
12        shrink = lambda n: f_then_g(shrink, grow, n)

```
