Dynamic Scope

Functional Programming

All functions are pure functions

No re-assignment and no mutable data types

Name-value bindings are permanent

Advantages of functional programming:

- \circ The value of an expression is independent of the order in which sub-expressions are evaluated
- * Sub-expressions can safely be evaluated in parallel or only on demand (lazily)
- Referential transparency: The value of an expression does not change when we substitute one of its subexpression with the value of that subexpression

But... no for/while statements! Can we make basic iteration efficient? Yes!

Tail Calls

Dynamic Scope

(q 3 7)

The way in which names are looked up in Scheme and Python is called lexical scope (or static scope) [You can see what names are in scope by inspecting the definition]

 $\textbf{Lexical scope:} \ \ \textbf{The parent of a frame is the environment in which a procedure was} \ \textit{defined}$

Dynamic scope: The parent of a frame is the environment in which a procedure was called

Special form to create dynamically scoped procedures (mu special form only exists in Project 4 Scheme)

(define f (tambda (x) (+ x y)))

(define g (lambda (x y) (f (+ x x))))

Lexical scope: The parent for f's frame is the global frame

Error: unknown identifier: y

Dynamic scope: The parent for f's frame is g's frame 13

Recursion and Iteration in Python

In Python, recursive calls always create new active frames

factorial(n, k) computes: n! * k

```
\begin{array}{c|c} \textbf{Time} & \textbf{Space} \\ \\ \text{def factorial(n, k):} & \\ \text{if } n = 0: \\ \text{if } n = 0: \\ \text{elsecturn k} \\ \\ \text{elsecturn factorial(n-1, k*n)} \\ \\ \text{def factorial(n, k):} \\ \text{while } n > 0: \\ \\ n, k = n-1, k*n \\ \\ \text{return k} \end{array}
```

Tail Calls

A procedure call that has not yet returned is active. Some procedure calls are tail calls. A Scheme interpreter should support an unbounded number of active tail calls using only a constant amount of space.

A tail call is a call expression in a tail context:

- The last body sub-expression in a lambda expression
- \bullet Sub-expressions 2 & 3 in a tail context \mathbf{if} expression
- All non-predicate sub-expressions in a tail context cond
 The last sub-expression in a tail context and, or, begin, or let

```
(define (factorial n k)
(if (= n 0) k
(factorial (- n 1)
(* k n))))
```

Tail Recursion

Tail Recursion

From the Revised Report on the Algorithmic Language Scheme:

"Implementations of Scheme are required to be properly tail-recursive. This allows the execution of an iterative computation in constant space, even if the iterative computation is described by a syntatically recursive procedure.

Interactive Dispr

Example: Length of a List

A call expression is not a tail call if more computation is still required in the calling procedure $% \left(1\right) =\left\{ 1\right\} =\left\{ 1\right\}$

Linear recursive procedures can often be re-written to use tail calls

Eval with Tail Call Optimization

The return value of the tail call is the return value of the current procedure call

Therefore, tail calls shouldn't increase the environment size

(Demo)

Map and Reduce

General Computing Machines

Tail Recursion Examples

Example: Reduce

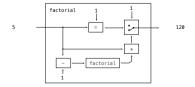

(define (reduce procedure s start) (if (null? s) start (reduce procedure (cdr s) ([procedure start (car s)])))

Recursive call is a tail call
Space depends on what procedure requires

(reduce * '(3 4 5) 2) 120
(reduce (lambda (x y) (cons y x)) '(3 4 5) '(2)) (5 4 3 2)

An Analogy: Programs Define Machines

Programs specify the logic of a computational device

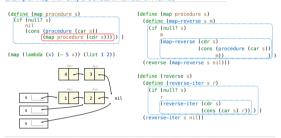

Which Procedures are Tail Recursive?

```
Which of the following procedures run in constant space? \Theta(1)
```

```
;; Return whether s contains v.
(define (contains s v)
(if (null? s)
;; Compute the length of s.
(define (length s)
(+ 1 (if (null? s)
                                                          false
(if (= v (car s))
           (length (cdr s))))))
;; Return the nth Fibonacci number.
                                                               (contains (cdr s) v)))
(define (fib n)
  (define (fib-iter current k)
                                                     ;; Return whether s has any repeated elements.
    (if (= k n)
                                                    (define (has-repeat s)
(if (null? s)
        (fib-iter (+ curren
                                                           false
                      (fib (- k 1)))
                                                           (if (contains? (cdr s) (car s))
 (if (= 1 n) 0 (fib-iter 1 2)))
                                                               (has-repeat (cdr s)))
```

Example: Map with Only a Constant Number of Frames

Interpreters are General Computing Machine

An interpreter can be parameterized to simulate any machine

Our Scheme interpreter is a universal machine

A bridge between the data objects that are manipulated by our programming language and the programming language itself

Internally, it is just a set of evaluation rules
